

# Mechanical Engineering: Year One Capstone Assesment

2019/2020

## Contents

<b>1</b>	<b>Blades</b>	<b>4</b>
1.1	For the blades of the wind turbine, composite materials are usually employed. Why is this the case? . . . . .	4
1.2	For the blades of the wind turbine, composite materials are usually employed. Why is this the case? . . . . .	4
1.3	What significant issues can you see with using composites in this engineering application? [For example, you could consider economic or environmental challenges] . . . . .	4
1.4	The power (W in J/s) produced by a wind turbine depends on blade length (B), the incoming wind speed (V), and air density ( $\rho$ ). Derive one dimensionless number relevant to the problem using W as the dependent parameter. Use this dimensionless number to comment on the implications of doubling the blade length. . . . .	4
1.5	Considering the answer above, discuss the trade-offs associated with choosing longer blades for a turbine of a fixed height. . . . .	5
<b>2</b>	<b>Gearbox (dynamics)</b>	<b>5</b>
2.1	Derive a simple relationship for the gear ratio expressed as a function of number of teeth in the sun and ring gears of an epicyclic (or planetary) gear train. . . . .	5
2.2	Perform a conceptual design of an epicyclic gear system for a 1.5 MW wind turbine if the three blades spin at a design speed of 12 rpm and the high-speed shaft in the generator needs to spin at 1680 rpm. Provide information on the configuration of your proposed planetary gear set (note: the 5 laws of planetary gearing – see the provided videos) and the input/output torque ratio that can be achieved by your system. Neglect friction and assume that the angular acceleration of the gears (which are rigid and non-deformable) is zero. You must indicate the number of teeth in each gear and provide a schematic drawing. . .	5
2.3	Wind gusts and turbulence lead to misalignment of the drive train and premature failure of the gear components. How could this be mitigated? . . . . .	5
2.4	Comment on the advantages/disadvantages of an epicyclic gear system in the context of a wind turbine gear box. . . . .	5

<b>3</b>	<b>Gearbox (materials)</b>	<b>5</b>
3.1	For the gears in the gearbox of the wind turbine, steel would normally be the material of choice. Why is this the case? . . . . .	5
3.2	There are many different grades of steel available – what particular properties of the steel might be required for a gearbox application, and what sorts of steel would be suitable therefore? . . . . .	5
3.3	The gears will be enclosed in a housing to help hold the mechanism together and prevent the ingress of contaminants. Suggest suitable materials for this housing, ensuring you provide justification for your suggestions (taking into account a range of factors including properties, and economic issues). Given your suggestions above, qualify these by providing consideration for how such an enclosure could be manufactured. What manufacturing processes might principally be required? . . . . .	5
<b>4</b>	<b>Tower</b>	<b>5</b>
4.1	The tower in the picture is a single tube which is also normally made of steel. Explain why this is likely to be manufactured from a different grade of steel to that used in the gearbox. What properties are needed in this particular context? . . . . .	5
<b>5</b>	<b>Energy generation</b>	<b>5</b>
5.1	Designers are considering the maximum power that could be generated by this turbine in two theoretical case studies. In case A, the incoming wind speed is 25 m/s and the air speed after passing through the blades is 15 m/s. In case B, the incoming wind speed is 20 m/s and the final speed is 12 m/s. Describe the concepts needed to estimate the maximum theoretical output of a wind turbine, and calculate the maximum theoretical power output for both these cases when the blade length is 37 m. Take the value of 1.2 kg/m <sup>3</sup> for air density. . . . .	5
5.2	Consider the various terms in the energy equation as they relate to a wind turbine. Describe briefly which terms are important for the wind turbine, and connect terms in the equation to the major sources of energy loss. Comment on the implications for wind turbine efficiency.	5
5.3	The world's most powerful commercial wind turbine today has a blade length of 82m and is rated at 9.5 MW. Comment briefly on the reasons why the numbers calculated using your theoretical approach above are far larger than this actual capacity. . . . .	5
<b>6</b>	<b>Energy storage</b>	<b>5</b>

6.1	In an offshore wind turbine facility, the excess energy generated is stored using a simple compressed air storage system. The wind turbine is mechanically coupled to a compressor that has a compression ratio of 200. The compressor takes in air from the surrounding at ambient pressure and temperature conditions ( $p_0$ , $T_0$ ) and performs a reversible adiabatic compression process. The output air from the compressor (at $p_1$ , $T_1$ ) undergoes a reversible isobaric heat removal process using a heat exchanger in order to reduce the temperature to $T_0$ . The air is then stored in a high-pressure storage facility. . . . .	5
6.2	Determine: . . . . .	5
6.2.1	heat and work transfers per unit mass for both the compression and heat removal processes . . . . .	5
6.2.2	the total entropy change per unit mass undergone by air . . . .	5
6.3	The heat removal in the above system is achieved by a refrigerator operating on a simple vapour compression cycle. This simple vapour compression refrigerator uses ammonia ( $\text{NH}_3$ ) as the working fluid. The evaporator pressure is $p_e$ and the condenser pressure is $p_c$ (where $p_c/p_e=6$ ). The working fluid leaves the evaporator dry-saturated and enters the compressor, where it is compressed reversibly and adiabatically. Condensation at constant pressure then takes place until the saturated liquid state is reached. This is followed by throttling to evaporator pressure. . . . .	5
6.4	Sketch the cycle on T-s and p-h diagrams . . . . .	5
6.4.1	the compressor delivery temperature, and . . . . .	5
6.4.2	the mass flow rate of the refrigerant . . . . .	5
<b>7</b>	<b>Final discussion</b>	<b>5</b>
7.1	Consider all the aspects covered above and compare the trade-offs in each of these categories during wind turbine design. You may also wish to consider how they are affected by the environment: water depth, ocean waves and seafloor structure. Reflect on the consequent additional challenges in building and maintaining offshore wind turbines. . . . .	5

# 1 Blades

- 1.1 For the blades of the wind turbine, composite materials are usually employed. Why is this the case?
- 1.2 For the blades of the wind turbine, composite materials are usually employed. Why is this the case?
- 1.3 What significant issues can you see with using composites in this engineering application? [For example, you could consider economic or environmental challenges]
- 1.4 The power ( $W$  in J/s) produced by a wind turbine depends on blade length ( $B$ ), the incoming wind speed ( $V$ ), and air density ( $\rho$ ). Derive one dimensionless number relevant to the problem using  $W$  as the dependent parameter. Use this dimensionless number to comment on the implications of doubling the blade length.

Using Buckingham Pi:

$$[W] = ML^2T^{-3} \quad (1)$$

$$[B] = L \quad (2)$$

$$[V] = LT^{-1} \quad (3)$$

$$[\rho] = ML^{-3} \quad (4)$$

$$W = B^a V^b \rho^c \quad (5)$$

$$ML^2T^{-3} = L^a L^b T^{-b} M^c L^{-3c} \quad (6)$$

$$c = 1, b = 3, a = 2 \quad (7)$$

$$W = B^2 V^3 \rho \quad (8)$$

$$k = \frac{W_1}{B^2 V^3 \rho} \text{ and } k = \frac{W_2}{4B^2 V^3 \rho} \quad (9)$$

$$W_1 = \frac{W_2}{4} \quad (10)$$

$$4W_1 = W_2 \quad (11)$$

- 1.5 Considering the answer above, discuss the trade-offs associated with choosing longer blades for a turbine of a fixed height.

## 2 Gearbox (dynamics)

- 2.1 Derive a simple relationship for the gear ratio expressed as a function of number of teeth in the sun and ring gears of an epicyclic (or planetary) gear train.
- 2.2 Perform a conceptual design of an epicyclic gear system for a 1.5 MW wind turbine if the three blades spin at a design speed of 12 rpm and the high-speed shaft in the generator needs to spin at 1680 rpm. Provide information on the configuration of your proposed planetary gear set (note: the 5 laws of planetary gearing – see the provided videos) and the input/output torque ratio that can be achieved by your system. Neglect friction and assume that the angular acceleration of the gears (which are rigid and non-deformable) is zero. You must indicate the number of teeth in each gear and provide a schematic drawing.
- 2.3 Wind gusts and turbulence lead to misalignment of the drive train and premature failure of the gear components. How could this be mitigated?
- 2.4 Comment on the advantages/disadvantages of an epicyclic gear system in the context of a wind turbine gear box.

## 3 Gearbox (materials)

- 3.1 For the gears in the gearbox of the wind turbine, steel would normally be the material of choice. Why is this the case?
- 3.2 There are many different grades of steel available – what particular properties of the steel might be required for a gearbox application, and what sorts of steel would be suitable therefore?
- 3.3 The gears will be enclosed in a housing to help hold the mechanism together and prevent the ingress of contaminants. Suggest suitable materials for this housing, ensuring you provide justification for your suggestions (taking into account a range of factors including properties, and economic issues). Given your suggestions
