

0.1 Derivation of Bending Equations

0.1.1 Equilibrium – Beam Bending Equations

Figure 1: Horizontal beam with vertical distributed load. We focus a section of the beam with the very small length δx .

y-direction

$$Q(x + \delta x) - Q(x) + w(x)\delta x = 0 \quad (1)$$

x-direction

$$M(x + \delta x) - M(x) - Q(x)\delta x + w(x) \cdot \delta x \cdot \frac{\delta x}{2} = 0 \quad (2)$$

We assume that δx is so small that no matter the distribution of the load on the beam, $w(x)$ is constant along the investigated beam section.

Rearranging the terms in the y direction yields:

$$\frac{Q(x + \delta x) - Q(x)}{\delta x} = -w(x) \quad (3)$$

Taking δx to the smallest limit (0), the above equation can be written as:

$$\delta x = 0 \quad (4)$$

$$\frac{dQ}{dx} = -w(x) \quad (5)$$

$$w(x) = -\frac{dQ}{dx} \quad (6)$$

The load w in the y direction is the derivative of the shear force Q . Integrating equation (6):

$$Q = - \int w \, dx \quad (7)$$

We consider the bending moment at the distance δx (right-side for the example). Rearranging the terms in the x direction yields:

$$\frac{M(x + \delta x) - M(x)}{\delta x} = Q(x) - \frac{1}{2}w(x)\delta x \quad (8)$$

Taking δx to the smallest limit (0), the above equation can be written as:

$$\delta x = 0 \quad (9)$$

$$Q(x) = \frac{dM}{dx} \quad (10)$$

$$(11)$$

The shear force Q is the derivative of the bending Moment M . Integrating equation (11):

$$M = \int Q \, dx \quad (12)$$

Example:

$$Q = - \int w \, dx \quad (13)$$

$$= -wx + Q_0 \quad (14)$$

$$(15)$$

$$M = \int Q \, dx \quad (16)$$

$$= \int (-wx + Q_0) \, dx \quad (17)$$

$$= -\frac{1}{2}wx^2 + Q_0 \cdot x + M_0 \quad (18)$$

Applying the boundary conditions:

$$M(0) = 0 \rightarrow -\frac{1}{2}w \cdot 0^2 + Q_0 \cdot 0 + M_0 = 0 \quad (19)$$

$$M_0 = 0 \quad (20)$$

$$(21)$$

$$M(l) = 0 \rightarrow -\frac{1}{2}wl^2 + Q_0 \cdot l + 0 = 0 \quad (22)$$

$$Q_0 = \frac{1}{2}wl \quad (23)$$

Overall:

$$Q = -wx + \frac{1}{2}wl \quad (24)$$

$$M = -\frac{1}{2}wx^2 + \frac{1}{2}wlx \quad (25)$$

Figure 2: The shear force and bending moment varying along x

0.2 Differential Equations for Deflection

0.2.1 Theory of Pure Bending

- The beam is initially straight and unstressed;
- The beam material is perfectly homogeneous and isotropic;
- Plane cross-sections remain plane before and after bending;
- Every cross-section in the beam is symmetrical about the plane of bending;
- There is no resultant force perpendicular to any cross-section.
- The elastic limit is nowhere exceeded;
- Young's Modulus for the material is the same in tension and compression;

0.2.2 Compatibility - Strains in Pure Bending

Consider a portion of the length dx from the beam subject to uniform bending.

Lower fibres stretch and upper fibres shorten. Hence, since cross-sections remain plane, there must be a plane where the fibre elongation is zero. This is called **neutral plane** (it is a plane because section is symmetrical) and the intersection with the plane of bending is called **neutral axis**.

If we indicate with R the radius of curvature of the neutral axis, along the neutral plane:

$$\overline{AB} = \widehat{AB} \quad (26)$$

$$\widehat{AB} = dx = R d\theta \quad (27)$$

For a generic plane CD, distant h from N.A.:

$$\widehat{CD} = (R + h) d\theta \quad (28)$$

The longitudinal strain of CD is given by:

$$\epsilon(h) = \frac{\text{elongation}}{\text{initial length}} = \frac{\widehat{CD} - \overline{CD}}{\overline{CD}} \quad (29)$$

$$(30)$$

$$= \frac{(R + h) \cdot d\theta - R \cdot d\theta}{R \cdot d\theta} = \frac{h}{R} \quad (31)$$

$$(32)$$

$$\epsilon(h) = \frac{h}{R} \quad (33)$$

Figure 3: Strains are distributed linearly across the section

Stresses and strains can be associated with each other. For most materials, under small deformation:

$$\sigma = E \cdot \epsilon \quad (34)$$

Where:

- σ is the stress
- E is the Young Modulus
- ϵ is the strain

Therefore, from equations (33) and (34):

$$\sigma_x(h) = E \frac{h}{R} \quad (35)$$

0.2.3 Constitutive - Stress-Curvature Relation

Stress is also distributed linearly across the section, being 0 at the neutral plane and maximum (in tension and compression) at the outer surfaces, where the distance from the neutral plane is maximum.

$$\sigma_{min} = E \frac{h_{min}}{R} \quad (36)$$

$$\sigma_{max} = E \frac{h_{max}}{R} \quad (37)$$

The minimum value is at the compression and the maximum value is at the tension. This just follows the convention; the tension is taken as positive and compression is taken as negative, in terms of the stress direction.

0.2.4 Equilibrium - Force-Stress Relation

Considering an elemental area dA , the force associated with bending stress is:

$$dF_x = \sigma_x \cdot dA \quad (38)$$

$$= E \frac{h}{R} \cdot dA \quad (39)$$

For the force equilibrium of the entire section:

$$\int_A dF_x = \int_A E \frac{h}{R} \cdot dA = 0 \quad (40)$$

$$(41)$$

E and R are constants, so they don't affect the integral and can be taken out. Hence the first moment of area is:

$$\int_A h \cdot dA = 0 \quad (42)$$

The first moment of area of a section is zero if it is calculated about the centroid. **The neutral axis corresponds to the centroid of the section.**

0.2.5 Equilibrium - Bending-Stress Relation

Considering an elemental area dA , the internal moment produced by the bending stress is:

$$dM = \sigma_x \cdot h \cdot dA \quad (43)$$

$$= dF_x \cdot h \quad (44)$$

$$= E \frac{h}{R} \cdot h \cdot dA \quad (45)$$

Moment of the entire section:

$$M = \int_A dM = \int_A E \frac{h^2}{R} \cdot dA = \frac{E}{R} \int_A h^2 \cdot dA \quad (46)$$

The second moment of area is:

$$\int_A h^2 \cdot dA = I \quad (47)$$

The second moment of area represents how easy or difficult it is to bend a beam, depending on the shape of the cross section. The overall relation is:

$$M = \frac{EI}{R} \quad (48)$$

This defines how the cross section, elastic modulus, curvature, and bending moment are related to each other.

0.2.6 Solid Mechanics Equations

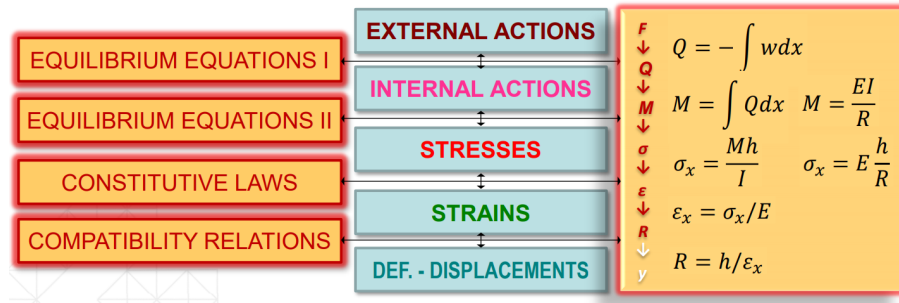

Figure 4: The relationships between Force, Shear Force, Bending Moment, Stress, Strain, Curvature

0.2.7 Geometric - Slope-Deflection Relation

Figure 5: The geometry of the beam under bending. The direction of the angle θ is based on the "right-hand rule".

For infinitesimal deformations:

$$dx \approx ds = -R \cdot d\theta \quad (49)$$

$$\frac{1}{R} = -\frac{d\theta}{dx} \quad (50)$$

The negative sign comes from the situation that the x axis direction is towards right while the angle (θ) direction is to the left. Hence, they are opposite. Since:

$$M = \frac{EI}{R} \quad (51)$$

$$\rightarrow M = -EI \frac{d\theta}{dx} \quad (52)$$

Assuming angle θ is small:

$$\theta \approx \tan(\theta) = \frac{dy}{dx} \quad (53)$$

- The load w in the y direction is the derivative of the shear force Q .
- The shear force Q is the derivative of the bending moment M .
- The bending moment M is proportional to the derivative of the slope θ .
- The slope θ is the derivative of the deflection y : $\theta = \frac{dy}{dx}$

0.2.8 Stresses Due to Shear Force

The shear force also produces stresses into the section (shear stresses). However:

- They are much lower than bending stresses
- They are zero at surfaces, where bending stresses are maximum
- Their effect on the deformation is negligible compared to bending stresses

In general, neglecting the shear stresses due to the shear force is a good approximation for both the calculation of failure and deflections.

0.2.9 Summary of Beam Bending Equations

Deflection:

$$y \quad (54)$$

Slope:

$$\theta = \frac{dy}{dx} \quad (55)$$

Bending Moment:

$$M = -EI \frac{d\theta}{dx} = -EI \frac{d^2 y}{dx^2} \quad (56)$$

Shear Force:

$$Q = \frac{dM}{dx} = -EI \frac{d^3 y}{dx^3} \quad (57)$$

Load Distribution:

$$w = -\frac{dQ}{dx} = EI \frac{d^4 y}{dx^4} \quad (58)$$

The equations above give a scenario of being given deflection y , and eventually finding load distribution w . However, the inverse can also occur where load distribution w is given, and the y can be found through integration:

Load Distribution

$$w \quad (59)$$

Shear Force:

$$Q = - \int w \cdot dx \quad (60)$$

Bending Moment:

$$M = \int Q \cdot dx = - \int \int w \cdot dx \, dx \quad (61)$$

Slope:

$$\theta = -\frac{1}{EI} \int M \cdot dx = \frac{1}{EI} \int \int \int w \cdot dx \, dx \, dx \quad (62)$$

Deflection:

$$y = \int \theta \cdot dx = \frac{1}{EI} \int \int \int \int w \cdot dx \, dx \, dx \, dx \quad (63)$$

0.2.10 Direct Integration Method

STEP 1: Determination of Support Reactions

Apply to the body the force and moment equilibrium equations to find support reactions (it is possible only if the system is statically determinate).

STEP 2: Determination of Deflection

1. Write bending moment expression
2. Use double integration on bending moment expression. This would result in 2 constants of integration.
3. Use boundary conditions to determinate constant of integration.

Example: Uniformly Distributed Load on a Cantilever Beam

Determination of Support Reactions:

$$\vec{R}_A = \begin{bmatrix} R_x \\ R_y \\ M_A \end{bmatrix}$$

$$\sum F_x : R_x = 0 \quad (64)$$

$$\sum F_y : R_y = wl \quad (65)$$

$$\sum M : M_A + wl \frac{l}{2} = 0 \quad (66)$$

$$M_A = -\frac{wl^2}{2} \quad (67)$$

Determination of Deflection:

Direct Integration:

$$Q = - \int w \cdot dx = -wx + Q_0 \quad (68)$$

$$(69)$$

$$M = \int Q \cdot dx \quad (70)$$

$$= \int (-wx + Q_0) dx \quad (71)$$

$$= -\frac{1}{2}wx^2 + Q_0x + M_0 \quad (72)$$

Boundary Conditions:

$$Q(0) = R_y = wl \quad (73)$$

$$\rightarrow Q_0 = wl \quad (74)$$

$$M(0) = M_A = -\frac{1}{2}wl^2 \quad (75)$$

$$\rightarrow M_0 = -\frac{1}{2}wl^2 \quad (76)$$

Therefore:

$$Q = -w(x + l) \quad (77)$$

$$M = -\frac{1}{2}wx^2 + wlx - \frac{1}{2}wl^2 \quad (78)$$

Relating Deflection to the Bending Moment:

$$M = -\frac{1}{2}wx^2 + wlx - \frac{1}{2}wl^2 \quad (79)$$

$$\theta = -\frac{1}{EI} \int M \cdot dx = -\frac{1}{EI} \left(-\frac{1}{6}wx^3 + \frac{1}{2}wlx^2 - \frac{1}{2}wl^2x \right) + \theta_0 \quad (80)$$

$$y = \int \theta \cdot dx = -\frac{1}{EI} \left(-\frac{1}{24}wx^4 + \frac{1}{6}wlx^3 - \frac{1}{4}wl^2x^2 \right) + \theta_0x + y_0 \quad (81)$$

$$(82)$$

Boundary Conditions:

$$\theta(0) = 0 \rightarrow \theta_0 = 0 \quad (83)$$

$$y(0) = 0 \rightarrow y_0 = 0 \quad (84)$$

Therefore:

$$y = \frac{1}{EI} \left(\frac{1}{24}wx^4 - \frac{1}{6}wlx^3 + \frac{1}{4}wl^2x^2 \right) \quad (85)$$

$$y_{max} = y(l) = \frac{wl^4}{8EI} \quad (86)$$
